

## howto transfer website template to upper level dir

Posted by seppo - 2009/03/24 18:14

---

If the master website is located at

[www.mydomain.com/master](http://www.mydomain.com/master)

and the new domains should be installed

[www.mydomain.com/newdomain](http://www.mydomain.com/newdomain)

or

[www.mydomain.com/jms/newdomain](http://www.mydomain.com/jms/newdomain)

how can this be done? From manage sites, this seems to work correctly, but when website template is used, it seems not to work - i tried many combinations, none of the worked.

All the domains created there seem to go to

[www.mydomain.com/master/multisites/](http://www.mydomain.com/master/multisites/)

-directory, without any symbolic links or any other way. Is it possible to change the multisites-directory used above?

It seems to work at manage sites, so should work also when using templates, but maybe I am missing something..

JMS can deploy website in any EXISTING directory.

In our example, we frequently used the /multisites/xxx directory because this directory is created by JMS to save the JMS configuration related to a specific site identifier.

If you want to deploy a website into /sitexxx you just have to create the directory before to deploy it. This will give you the [www.domain.com/sitexxx](http://www.domain.com/sitexxx)

If for example you want to create such structure when building a website from the front-end, you can use the specific script fields that are present in the menu type "multisites" and use the billable website functionality to execute such specific scripts or plugins.
